APPENDIX 2

NPWS (2014) SITE SYNOPSIS: RIVER BOYNE AND RIVER BLACKWATER SAC 002299.

NPWS (2021) CONSERVATION OBJECTIVES: RIVER BOYNE AND RIVER BLACKWATER SAC 002299. VERSION 1. NATIONAL PARKS AND WILDLIFE SERVICE, DEPARTMENT OF HOUSING, LOCAL GOVERNMENT AND HERITAGE.

NATIONAL BIODIVERSITY DATA CENTRE
SPECIES DATA AND 1KM GRID REPORT

SITE SYNOPSIS

Site Name: River Boyne and River Blackwater SAC

Site Code: 002299

This site comprises the freshwater element of the River Boyne as far as the Boyne Aqueduct, the Blackwater as far as Lough Ramor and the Boyne tributaries including the Deel, Stoneyford and Tremblestown Rivers. These riverine stretches drain a considerable area of Meath and Westmeath, and smaller areas of Cavan and Louth. The underlying geology is Carboniferous Limestone for the most part, with areas of Upper, Lower and Middle well represented. In the vicinity of Kells Silurian Quartzite is present while close to Trim are Carboniferous Shales and Sandstones. There are many large towns adjacent to but not within the site, including Slane, Navan, Kells, Trim, Athboy and Ballivor.

The site is a Special Area of Conservation (SAC) selected for the following habitats and/or species listed on Annex I / II of the E.U. Habitats Directive (* = priority; numbers in brackets are Natura 2000 codes):

[7230] Alkaline Fens
[91E0] Alluvial Forests*
[1099] River Lamprey (*Lampetra fluviatilis*)
[1106] Atlantic Salmon (*Salmo salar*)
[1355] Otter (*Lutra lutra*)

The main areas of alkaline fen in this site are concentrated in the vicinity of Lough Shesk, Freehan Lough and Newtown Lough. The hummocky nature of the local terrain produces frequent springs and seepages which are rich in lime. A series of base-rich marshes have developed in the poorly-drained hollows, generally linked with these three lakes. Open water is usually fringed by Bulrush (*Typha latifolia*), Common Club-rush (*Scirpus lacustris*) or Common Reed (*Phragmites australis*), and this last species also extends shorewards where a dense stand of Great Fen-sedge (*Cladium mariscus*) frequently occurs. This in turn grades into a sedge and grass community (*Carex* spp. and Purple Moor-grass, *Molinia caerulea*), or one dominated by Black Bog-rush (*Schoenus nigricans*). An alternative aquatic/terrestrial transition is a floating layer of vegetation. This is normally based on Bogbean (*Menyanthes trifoliata*) and Marsh Cinquefoil (*Potentilla palustris*). Other species gradually become established on this cover, especially plants tolerant of low nutrient status e.g. bog mosses (*Sphagnum* spp.). Diversity of plant and animal life is high in the fen and the flora includes many rarities. Plants of interest include Narrow-leaved Marsh-orchid (*Dactylorhiza traunsteineri*), Fen Bedstraw (*Galium uliginosum*), Cowbane (*Cicuta virosa*), Frogbit (*Hydrocharis morsus-ranae*) and Least Bur-reed (*Sparganium minimum*). These species tend to be restricted in their distribution in Ireland. Also notable is the

abundance of aquatic stoneworts (*Chara* spp.) which are characteristic of calcareous wetlands.

The rare plant Round-leaved Wintergreen (*Pyrola rotundifolia*) occurs around Newtown Lough. This species is listed in the Red Data Book and this site represents its only occurrence in Co. Meath.

Wet woodland fringes many stretches of the Boyne. The Boyne River Islands are a small chain of three islands situated 2.5 km west of Drogheda. The islands were formed by the build-up of alluvial sediment in this part of the river where water movement is sluggish. All of the islands are covered by dense thickets of wet, willow (*Salix* spp.) woodland, with the following species occurring: Osier (*S. viminalis*), Crack Willow (*S. fragilis*), White Willow (*S. alba*), Purple Willow (*Salix purpurea*) and Rusty Willow (*S. cinerea* subsp. *oleifolia*). A small area of Alder (*Alnus glutinosa*) woodland is found on soft ground at the edge of the canal in the north-western section of the islands. Along other stretches of the rivers of the site Rusty Willow scrub and pockets of wet woodland dominated by Alder have become established, particularly at the river edge of mature deciduous woodland. Ash (*Fraxinus excelsior*) and Downy Birch (*Betula pubescens*) are common in the latter, and the ground flora is typical of wet woodland with Meadowsweet (*Filipendula ulmaria*), Wild Angelica (*Angelica sylvestris*), Yellow Iris (*Iris pseudacorus*), horsetails (*Equisetum* spp.) and occasional tussocks of Greater Tussock-sedge (*Carex paniculata*).

The dominant habitat along the edges of the river is freshwater marsh, and the following plant species occur commonly in these areas: Yellow Iris, Creeping Bent (*Agrostis stolonifera*), Canary Reed-grass (*Phalaris arundinacea*), Marsh Bedstraw (Galium palustre), Water Mint (*Mentha aquatica*) and Water Forget-me-not (*Myosotis scorpioides*). In the wetter areas Common Meadow-rue (*Thalictrum flavum*) is found. In the vicinity of Dowth, Fen Bedstraw (*Galium uliginosum*), a scarce species mainly confined to marshy areas in the midlands, is common in this vegetation. Swamp Meadow-grass (*Poa palustris*) is an introduced plant which has spread into the wild (naturalised) along the Boyne approximately 5 km south-west of Slane. It is a rare species which is listed in the Red Data Book and has been recorded among freshwater marsh vegetation on the banks of the Boyne in this site. The only other record for this species in the Republic of Ireland is from a site in Co. Monaghan.

The secondary habitat associated with the marsh is wet grassland and species such as Tall Fescue (*Festuca arundinacea*), Silverweed (*Potentilla anserina*), Creeping Buttercup (*Ranunculus repens*), Meadowsweet and Meadow Vetchling (*Lathyrus pratensis*) are well represented. Strawberry Clover (*Trifolium fragiferum*), a plant generally restricted to coastal locations in Ireland, has been recorded from wet grassland vegetation at Trim. At Rossnaree river bank on the River Boyne, Round-Fruited Rush (*Juncus compressus*) is found in alluvial pasture, which is generally periodically flooded during the winter months. This rare plant is only found in three counties in Ireland.

Along much of the Boyne and along tributary stretches are found areas of mature deciduous woodland on the steeper slopes above the floodplain marsh or wet woodland vegetation. Many of these are planted in origin. However the steeper areas of King Williams Glen and Townley Hall wood have been left unmanaged and now have a more natural character. East of Curley Hole the woodland has a natural appearance with few conifers. Broadleaved species include oaks (*Quercus* spp.), Ash, willows, Hazel (*Corylus avellana*), Sycamore (*Acer pseudoplatanus*), Holly (*Ilex aquifolium*), Horse-chestnut (*Aesculus hipposcastanum*) and the shrubs Hawthorn (*Crataegus monogyna*), Blackthorn (*Prunus spinosa*) and Elder (*Sambucus nigra*). South-west of Slane and in Dowth, some more exotic tree species such as Beech (*Fagus sylvatica*), and occasionally Lime (*Tilia cordata*), are seen. The coniferous trees Larch (*Larix* sp.) and Scots Pine (*Pinus sylvestris*) also occur. The woodland ground flora includes Barren Strawberry (*Potentilla sterilis*), Enchanter's-nightshade (*Circaea lutetiana*) and Ground-ivy (*Glechoma hederacea*), along with a range of ferns. Variation occurs in the composition of the canopy - for example, in wet patches alongside the river, White Willow and Alder form the canopy.

Other habitats present along the Boyne and Blackwater include lowland dry grassland, improved grassland, reedswamp, weedy waste ground, scrub, hedge, drainage ditch and canal. In the vicinity of Lough Shesk, the dry slopes of the morainic hummocks support grassland vegetation which, in some places, is partially colonised by Gorse (*Ulex europaeus*) scrub. Those grasslands which remain unimproved for pasture are species-rich, with Common Knapweed (*Centaurea nigra*), Creeping Thistle (*Cirsium arvense*) and Ribwort Plantain (*Plantago lanceolata*) commonly present. Fringing the canal alongside the Boyne south-west of Slane are areas with Reed Sweet-grass (*Glyceria maxima*), Great Willowherb (*Epilobium hirsutum*) and Meadowsweet.

The Boyne and its tributaries form one of Ireland's premier game fisheries and the area offers a wide range of angling, from fishing for spring salmon and grilse to seatrout fishing and extensive brown trout fishing. Atlantic Salmon (*Salmo salar*) use the tributaries and headwaters as spawning grounds. Although this species is still fished commercially in Ireland, it is considered to be endangered or locally threatened elsewhere in Europe and is listed on Annex II of the Habitats Directive. Atlantic Salmon run the Boyne almost every month of the year. The Boyne is most important as it represents an eastern river which holds large three-sea-winter fish from 20-30 lb. These fish generally arrive in February, with smaller spring fish (10 lb) arriving in April/May. The grilse come in July, water permitting. The river gets a further run of fish in late August and this run would appear to last well after the fishing season. The salmon fishing season lasts from 1st March to 30th September.

The Blackwater is a medium sized limestone river which is still recovering from the effects of the arterial drainage scheme of the 1970s. Salmon stocks have not recovered to the numbers that existed pre-drainage. The Deel, Riverstown, Stoneyford and Tremblestown Rivers are all spring-fed, with a continuous high volume of water. They are difficult to fish because some areas are overgrown, while others have been affected by drainage with resultant high banks.

This site is also important for the populations of two other species listed on Annex II of the E.U. Habitats Directive which it supports, namely River Lamprey (*Lampetra fluviatilis*), which is present in the lower reaches of the Boyne River, and Otter (*Lutra lutra*), which can be found throughout the site. In addition, the site also supports many more of the mammal species occurring in Ireland. Those which are listed in the Irish Red Data Book include Pine Marten, Badger and Irish Hare. Common Frog, another Red Data Book species, also occurs within the site. All of these animals, with the addition of the Stoat and Red Squirrel, which also occur within the site, are protected under the Wildlife Act, 1976.

Whooper Swans winter regularly at several locations along the Boyne and Blackwater Rivers. Known sites are at Newgrange (approx. 20 in recent winters), near Slane (20+ in recent winters), Wilkinstown (several records of 100+) and River Blackwater from Kells to Navan (104 at Kells in winter 1996/97, 182 at Headfort in winter 1997/98, 200-300 in winter 1999/00). The available information indicates that there is a regular wintering population of Whooper Swans based along the Boyne and Blackwater River valleys. The birds use a range of feeding sites but roosting sites are not well known. The population is substantial, certainly of national, and at times international, importance. Numbers are probably in the low hundreds.

Intensive agriculture is the main land use along the site. Much of the grassland is in very large fields and is improved. Silage harvesting is carried out. The spreading of slurry and fertiliser poses a threat to the water quality of this salmonid river and to the lakes. In the more extensive agricultural areas sheep grazing is carried out.

Fishing is a main tourist attraction on the Boyne and Blackwater and there are a number of Angler Associations, some with a number of beats. Fishing stands and styles have been erected in places. The Eastern Regional Fishery Board have erected fencing along selected stretches of the river as part of their salmonid enhancement programme. Parts of the river system have been arterially dredged. In 1969 an arterial dredging scheme commenced and disrupted angling for 18 years. The dredging altered the character of the river completely and resulted in many areas in very high banks. The main channel from Drogheda upstream to Navan was left untouched, as were a few stretches on the Blackwater. Ongoing maintenance dredging is carried out along stretches of the river system where the gradient is low. This is extremely destructive to salmonid habitat in the area. Drainage of the adjacent river systems also impacts on the many small wetland areas throughout the site. The River Boyne is a designated Salmonid Water under the E.U. Freshwater Fish Directive.

The site supports populations of several species listed on Annex II of the E.U. Habitats Directive, and habitats listed on Annex I of this Directive, as well as examples of other important habitat types. Although the wet woodland areas appear small there are few similar examples of this type of alluvial wet woodland remaining in the country, particularly in the north-east. The semi-natural habitats, particularly the strips of woodland which extend along the river banks, and the marsh and wet

grasslands, increase the overall habitat diversity and add to the ecological value of the site, as does the presence of a range of Red Data Book plant and animal species and the presence of nationally rare plant species.

NPWS (2021) Conservation Objectives: River Boyne and River Blackwater SAC 002299. Version 1. National Parks and Wildlife Service, Department of Housing, Local Government and Heritage.

Series Editors: Rebecca Jeffrey and Christina Campbell
ISSN 2009-4086

Introduction

The overall aim of the Habitats Directive is to maintain or restore the favourable conservation status of habitats and species of community interest. These habitats and species are listed in the Habitats and Birds Directives and Special Areas of Conservation and Special Protection Areas are designated to afford protection to the most vulnerable of them. These two designations are collectively known as the Natura 2000 network.

European and national legislation places a collective obligation on Ireland and its citizens to maintain habitats and species in the Natura 2000 network at favourable conservation condition. The Government and its agencies are responsible for the implementation and enforcement of regulations that will ensure the ecological integrity of these sites.

A site-specific conservation objective aims to define favourable conservation condition for a particular habitat or species at that site.

The maintenance of habitats and species within Natura 2000 sites at favourable conservation condition will contribute to the overall maintenance of favourable conservation status of those habitats and species at a national level.

Favourable conservation status of a habitat is achieved when:

- its natural range, and area it covers within that range, are stable or increasing, and
- the specific structure and functions which are necessary for its long-term maintenance exist and are likely to continue to exist for the foreseeable future, and
- the conservation status of its typical species is favourable.

The favourable conservation status of a species is achieved when:

- population dynamics data on the species concerned indicate that it is maintaining itself on a long-term basis as a viable component of its natural habitats, and
- the natural range of the species is neither being reduced nor is likely to be reduced for the foreseeable future, and
- there is, and will probably continue to be, a sufficiently large habitat to maintain its populations on a long-term basis.

Notes/Guidelines:

1. The targets given in these conservation objectives are based on best available information at the time of writing. As more information becomes available, targets for attributes may change. These will be updated periodically, as necessary.
2. An appropriate assessment based on these conservation objectives will remain valid even if the targets are subsequently updated, providing they were the most recent objectives available when the assessment was carried out. It is essential that the date and version are included when objectives are cited.
3. Assessments cannot consider an attribute in isolation from the others listed for that habitat or species, or for other habitats and species listed for that site. A plan or project with an apparently small impact on one attribute may have a significant impact on another.
4. Please note that the maps included in this document do not necessarily show the entire extent of the habitats and species for which the site is listed. This should be borne in mind when appropriate assessments are being carried out.
5. When using these objectives, it is essential that the relevant backing/supporting documents are consulted, particularly where instructed in the targets or notes for a particular attribute.

Qualifying Interests

**** indicates a priority habitat under the Habitats Directive***

002299	River Boyne and River Blackwater SAC
1099	River Lamprey *Lampetra fluviatilis*
1106	Salmon *Salmo salar*
1355	Otter *Lutra lutra*
7230	Alkaline fens
91E0	Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior* (Alno-Padion, Alnion incanae, Salicion albae)*

Please note that this SAC overlaps with Boyne Estuary SPA (004080) and River Boyne and River Blackwater SPA (004232). The SAC is also adjacent to Boyne Coast and Estuary SAC (001957). See map 2. The conservation objectives for this site should be used in conjunction with those for the overlapping and adjacent sites as appropriate.

7230 Alkaline fens

To maintain the favourable conservation condition of Alkaline fens in River Boyne and River Blackwater SAC, which is defined by the following list of attributes and targets:

Attribute	Measure	Target	Notes
Habitat area	Hectares	Area stable or increasing, subject to natural processes	Alkaline fen has not been mapped in detail for River Boyne and River Blackwater SAC and thus the exact total current area of the qualifying habitat in the SAC is currently unknown. The main areas of alkaline fen in the SAC are documented to occur in the vicinity of Lough Shesk, Freekan Lough, Newtown Lough in the upper reaches of the Stonyford River. At Lough Shesk, the habitat is particularly well-represented and there is a good example of succession from open water to fen-type habitat (NPWS internal files)
Habitat distribution	Occurrence	No decline, subject to natural processes	See the notes for habitat area above
Ecosystem function: soil nutrients	Soil pH and appropriate nutrient levels at a representative number of monitoring stops	Maintain soil pH and nutrient status within natural ranges	Relevant nutrients and their natural ranges are yet to be defined. However, nitrogen deposition is noted as being relevant to this habitat in NPWS (2013). See also Bobbink and Hettelingh (2011). Increased nutrients can lead to changes in plant and invertebrate species through competition and subsequent structural changes to micro-habitat. These nutrients favour growth of grasses rather than forbs and mosses and leads to a higher and denser sward
Ecosystem function: peat formation	Percentage cover of peat-forming vegetation and water table levels	Maintain active peat formation, where appropriate	In order for peat to form, water levels need to be slightly below or above the soil surface for c.90% of the time
Ecosystem function: hydrology - groundwater levels	Water levels (centimetres); duration of levels; hydraulic gradients; water supply	Maintain, or where necessary restore, appropriate natural hydrological regimes necessary to support the natural structure and functioning of the habitat	Fen habitats require high groundwater levels (i.e. water levels at or above the ground surface) for a large proportion of the calendar year (i.e. duration of mean groundwater level). Fen groundwater levels are controlled by regional groundwater levels in the contributing catchment area (which sustain the hydraulic gradients of the fen groundwater table). Regional abstraction of groundwater may affect fen groundwater levels
Ecosystem function: hydrology - surface water flow	Drain density and form	Maintain, or where necessary restore, as close as possible to natural or semi-natural, drainage conditions	Drainage, either within or surrounding the fen habitat, can result in the drawdown of the groundwater table. The depth, geometry and density of drainage (hydromorphology) will indicate the scale and impact on fen hydrology. Drainage can result in loss of characteristic species and transition to drier habitats
Ecosystem function: water quality	Various	Maintain appropriate water quality, particularly pH and nutrient levels, to support the natural structure and functioning of the habitat	Fens receive natural levels of nutrients (e.g. iron, magnesium and calcium) from water sources. However, they are generally poor in nitrogen and phosphorus, with the latter tending to be the limiting nutrient under natural conditions. Water supply should be also relatively calcium-rich
Vegetation composition: community diversity	Abundance of variety of vegetation communities	Maintain variety of vegetation communities, subject to natural processes	The entire diversity of alkaline fen vegetation communities present in the SAC is currently unknown. Information on the vegetation communities associated with alkaline fens is provided by O'Neill et al. (in prep.). See also the Irish Vegetation Classification (Perrin, 2018; www.biodiversityireland.ie/projects/ivc-classification-explorer)

Vegetation composition: typical brown mosses	Percentage cover at a representative number of monitoring stops	Maintain adequate cover of typical brown moss species	For lists of typical bryophyte species, including high quality indicator species, see O'Neill et al. (in prep.). Species recorded at Lough Shesk and Newtown Lough include: *Calliergon giganteum, Scorpidium scorpioides, Campylium stellatum, Bryum pseudotriquetrum, Fissidens adianthoides, Scorpidium scorpioides, Calliergonella cuspidata* and *Ctenidium molluscum* (NPWS internal files)
Vegetation composition: typical vascular plants	Percentage cover at a representative number of monitoring stops	Maintain adequate cover of typical vascular plant species	For lists of typical vascular plant species for the different vegetation communities, including high quality indicators, see O'Neill et al. (in prep.). Typical species recorded in the habitat in the SAC include black bog-rush (*Schoenus nigricans*), dioecious sedge (*C. dioica*) and common butterwort (*Pinguicula vulgaris*) (NPWS internal files)
Vegetation composition: native negative indicator species	Percentage cover at a representative number of monitoring stops	Cover of native negative indicator species at insignificant levels	Negative indicators include species not characteristic of the habitat and species indicative of undesirable activities such as overgrazing, undergrazing, nutrient enrichment, agricultural improvement or impacts on hydrology. Native negative indicators may include *Anthoxanthum odoratum, Epilobium hirsutum, Holcus lanatus, Juncus effusus, Phragmites australis* and *Ranunculus repens*. See O'Neill et al. (in prep.)
Vegetation composition: non-native species	Percentage cover at a representative number of monitoring stops	Cover of non-native species less than 1%	Attribute and target based on O'Neill et al. (in prep.). Non-native species can be invasive and have deleterious effects on native vegetation. A low target is set as non-native species can spread rapidly and are most easily dealt with when still at lower abundances
Vegetation composition: native trees and shrubs	Percentage cover in local vicinity of a representative number of monitoring stops	Cover of scattered native trees and shrubs less than 10%	Attribute and target based on O'Neill et al. (in prep.). Scrub and trees will tend to invade if fen conditions become drier
Vegetation composition: algal cover	Percentage cover at, and in local vicinity of, a representative number of monitoring stops	Cover of algae less than 2%	Attribute and target based on O'Neill et al. (in prep.). Algal cover is indicative of nutrient enrichment from multiple sources (McBride et al., 2011)
Vegetation structure: vegetation height	Percentage cover at a representative number of monitoring stops	At least 50% of the live leaves/flowering shoots are more than either 5cm or 15cm above ground surface depending on community type	Attribute and target based on O'Neill et al. (in prep.). While grazing may be appropriate in this habitat, excessive grazing can reduce the ability of plant species to regenerate reproductively and maintain species diversity, especially if flowering shoots are cropped during the growing season
Physical structure: disturbed bare ground	Percentage cover at, and in local vicinity of, a representative number of monitoring stops	Cover of disturbed bare ground not more than 10%	Attribute and target based on O'Neill et al. (in prep.). While grazing may be appropriate in this habitat, excessive areas of disturbed bare ground may develop due to unsuitable grazing regimes. Disturbance can include hoof marks, wallows, human footprints, vehicle and machinery tracks. Excessive disturbance can result in loss of characteristic species and presage erosion for peatlands
Physical structure: tufa formations	Percentage cover in local vicinity of a representative number of monitoring stops	Disturbed proportion of vegetation cover where tufa is present is less than 1%	Attribute and target based on O'Neill et al. (in prep.)
Indicators of local distinctiveness	Occurrence and population size	No decline in distribution or population sizes of rare, threatened or scarce species associated with the habitat; maintain features of local distinctiveness, subject to natural processes	This includes species on the Flora (Protection) Order, 2015 and/or Red Lists (Byrne et al., 2009; Regan et al., 2010; Lockhart et al., 2012; Wyse Jackson et al., 2016, etc.). The Near Threatened species (Wyse Jackson et al., 2016) round-leaved wintergreen (*Pyrola rotundifolia*) has been recorded in the habitat around Newtown Lough in the SAC (NPWS internal files)
Transitional areas between fen and adjacent habitats	Hectares; distribution	Maintain adequate transitional areas to support/protect the alkaline fen ecosystem and the services it provides	In many cases, fens transition to other wetland habitats. It is important that the transitional areas between fens and other habitats are maintained in as natural condition as possible in order to protect the functioning of the fen

91E0 Alluvial forests with Alnus glutinosa and Fraxinus excelsior (Alno-Padion, Alnion incanae, Salicion albae)*

To restore the favourable conservation condition of Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior* (Alno-Padion, Alnion incanae, Salicion albae)* in River Boyne and River Blackwater SAC, which is defined by the following list of attributes and targets:

Attribute	Measure	Target	Notes
Habitat area	Hectares	Area stable or increasing, subject to natural processes. See map 3 for surveyed woodland areas	Alluvial forests with *Alnus glutinosa* and *Fraxinus excelsior* (Alno-Padion, Alnion incanae, Salicion albae)* is present within River Boyne and River Blackwater SAC. As part of the National Survey of Native Woodlands (NSNW), the sub-sites Grove Island (NSNW site code 688) and Yellow Island (752) were surveyed by Perrin et al. (2008). Yellow Island (code 752) was also included in national monitoring surveys (O'Neill and Barron, 2013; Daly et al., in prep.). Map 3 shows the minimum area of alluvial forests within the SAC, which is estimated to be 16.7ha (Perrin et al., 2008; Daly et al., in prep.). It is important to note that further unsurveyed areas may be present within the SAC
Habitat distribution	Occurrence	No decline, subject to natural processes. The surveyed woodland locations are shown on map 3	Distribution based on Perrin et al. (2008) and Daly et al. (in prep.). It is important to note that further unsurveyed areas may be present within the SAC
Woodland size	Hectares	Area stable or increasing. Where topographically possible, "large" woods at least 25ha in size and "small" woods at least 3ha in size	The target areas for individual woodlands aim to reduce habitat fragmentation and benefit those species requiring 'deep' woodland conditions (Peterken, 2002). In some cases, topographical constraints may restrict expansion
Woodland structure: cover and height	Percentage; metres; centimetres	Total canopy cover at least 30%; median canopy height at least 7m; native shrub layer cover 10-75%; native herb/dwarf shrub layer cover at least 20% and height at least 20cm; bryophyte cover at least 4%	The target aims for a diverse structure with a canopy containing mature trees, shrub layer with semi-mature trees and shrubs, and well-developed field layer (herbs, graminoids and dwarf shrubs) and ground layer (bryophytes). Assessment criteria are described in Daly et al. (in prep.) and O'Neill and Barron (2013)
Woodland structure: community diversity and extent	Hectares	Maintain diversity and extent of community types	The Boyne River Islands are an example of gallery forests of willows (Salicion albae), which occur alongside river channels and on river islands, where tree roots are almost continuously submerged (Daly et al., in prep.). Grove Island (NSNW site code 688) and Yellow Island (752) were assigned by Perrin et al. (2008) to the *Salix triandra – Urtica dioica* vegetation type (2h) of the *Fraxinus excelsior – Hedera helix* group. This corresponds to the *Salix fragilis – Calystegia sepium* sub-community (WL3Di) of the Irish Vegetation Classification (Perrin, 2016; www.biodiversityireland.ie/projects/ivc-classification-explorer)
Woodland structure: natural regeneration	Seedling: sapling: pole ratio	Seedlings, saplings and pole age-classes of target species for 91E0* woodlands and other native tree species occur in adequate proportions to ensure survival of woodland canopy	The target species for 91E0* are alder (*Alnus glutinosa*), ash (*Fraxinus excelsior*) and willows (*Salix* spp.). Assessment criteria are described in Daly et al. (in prep.) and O'Neill and Barron (2013)

Hydrological regime: flooding depth/height of water table	Metres	Appropriate hydrological regime necessary for maintenance of alluvial vegetation	Periodic flooding is essential to maintain alluvial woodlands along river and lake floodplains, but not for woodland around springs/seepage areas. Much of the river channel within the SAC was subject to arterial drainage schemes. Natural flood-plains now exist along only limited stretches of river (NPWS internal files)
Woodland structure: dead wood	Number per hectare	At least 19 stems/ha of dead wood of at least 20cm diameter	Dead wood is a valuable resource and an integral part of a healthy, functioning woodland ecosystem
Woodland structure: veteran trees	Number per hectare	No decline	Veteran trees are important habitats for bryophytes, lichens, saproxylic organisms and some bird species. Their retention is important to ensure continuity of habitats/niches and propagule sources
Woodland structure: indicators of local distinctiveness	Occurrence; population size	No decline in distribution and, in the case of red listed and other rare or localised species, population size	Includes ancient or long-established woodlands (see Perrin and Daly, 2010), archaeological and geological features as well as red listed and other rare or localised species
Woodland structure: indicators of overgrazing	Occurrence	All five indicators of overgrazing absent	There are five indicators of overgrazing within 91E0*: topiary effect on shrubs and young trees, browse line on mature trees, abundant dung, severe recent bark stripping, and trampling (Daly et al., in prep.)
Vegetation composition: native tree cover	Percentage	No decline. Native tree cover at least 90% of canopy; target species cover at least 50% of canopy	The target species for 91E0* are alder (*Alnus glutinosa*), ash (*Fraxinus excelsior*) and willows (*Salix* spp.) (Daly et al., in prep.; O'Neill and Barron, 2013)
Vegetation composition: typical species	Occurrence	At least 1 target species for 91E0* woodlands present; at least 6 positive indicator species for 91E0* woodlands present	A variety of typical native species should be present, depending on woodland type. The target species for 91E0* are alder (*Alnus glutinosa*), ash (*Fraxinus excelsior*) and willows (*Salix* spp.). Positive indicator species for 91E0* are listed in Daly et al. (in prep.) and O'Neill and Barron (2013)
Vegetation composition: negative indicator species	Occurrence	Negative indicator species cover not greater than 10%; regeneration of negative indicator species absent	Negative indicator species (i.e. any non-native species, including herbaceous species) should be absent or under control. The canopy at Grove Island (NSNW site code 688) and Yellow Island (752) is dominated by a range of *Salix* spp. (*S. cinerea, S. triandra, S. fragilis, S. viminalis*) (Perrin et al., 2008). Although the latter two are not native to Ireland, an exception is made for these species where they occur within gallery woodland (Daly et al., in prep.). Perrin et al. (2008) recorded some sycamore (*Acer pseudoplatanus*) in the canopy at Grove Island (NSNW site code 688). Daly et al. (in prep.) found that the recent arrival of the invasive non-native herb Himalayan balsam (*Impatiens glandulifera*) at Yellow Island (752) has caused significant negative impacts to the alluvial forest habitat
Vegetation composition: problematic native species	Percentage	Cover of common nettle (*Urtica dioica*) less than 75%	Common nettle (*Urtica dioica*) is a positive indicator species for 91E0* but, in some cases, it may become excessively dominant. Increased light and nutrient enrichment are factors which favour proliferation of common nettle (Daly et al., in prep.)

1099 River Lamprey *Lampetra fluviatilis*

To restore the favourable conservation condition of River Lamprey (*Lampetra fluviatilis*) in River Boyne and River Blackwater SAC, which is defined by the following list of attributes and targets:

Attribute	Measure	Target	Notes
Distribution	Percentage of river accessible	Restore access to all water courses down to first order streams	Artificial barriers can block or impede the passage of upstream migrating lamprey, thereby restricting access to spawning areas (Gargan et al., 2011; Rooney et al., 2015). There are a number of weirs along the lower sections of the Boyne main channel, the most substantial of these are located at Slane and downstream of Navan at Blackcastle. Efforts to trap adult river lamprey were undertaken at four locations throughout the catchment during November 2014 to April 2015. This was augmented in April 2015 by an extensive fyke-netting survey (n=26 sites). No adult river lamprey were encountered, with the only record to date being a dead individual from the River Boyne at Slane in late March 2015 (Gallagher et al., 2016). On the Boyne main channel, there is ideal spawning habitat both upstream and downstream of the weir at Blackcastle but spawning has not been observed at these locations to date
Distribution of larvae	Number of positive sites in 2nd order channels (and greater), downstream of spawning areas	Not less than 50% of sample sites with suitable habitat positive for larval brook/river lamprey	It is not possible to distinguish between larval brook and river lamprey in the field and they are therefore considered together in assessing conservation status. A survey of the Boyne catchment in 2015 recorded n=583 *Lampetra* spp. larvae from n=102 sites (Gallagher et al., 2016). As stated, the weirs in the lower main stem are a significant impediment to river lamprey passage and, for this reason, these larvae are considered to be mainly, if not all, brook lamprey. To achieve favourable condition *Lampetra* spp. should, as a minimum, be present in not less than 50% of all sampling sites surveyed with suitable habitat present within the natural range (JNCC, 2015). *Lampetra* spp. larvae were recorded from 72% of sites indicating a pass for this target. Distribution remained similar to a 2005 survey (O'Connor, 2006) although larvae continued to be absent from the Boycetown and Skane Rivers, as well as the upper reaches of the Kells Blackwater system
Population structure of larvae	Number of age/size classes	At least three age/size classes of larval brook/river lamprey present	The target of at least three age/size classes is based on guidance from JNCC (2015). Larvae typically range from 10-150mm in length and this corresponds to up to six age classes. A broad range of size classes (12-153mm), including young-of-year larvae, was recorded from the 2015 Boyne catchment-wide survey indicating a pass for this target. However, given the issue of artificial barriers on the River Boyne, it is likely that this value pertains to brook lamprey, as previously stated
Larval lamprey density in fine sediment	Larval lamprey/m²	Mean density of brook/river larval lamprey in sites with suitable habitat more than 5/m²	A target mean density of more than 5/m² larvae in sites with suitable habitat is required to achieve favourable condition (JNCC, 2015). In the Boyne survey a mean density of 6/m² *Lampetra* spp. larvae (n=583) was obtained. A number of tributaries did not achieve a pass for this target, including the Athboy/Tremblestown, Boycetown, Deel, Skane and Stonyford Rivers. Again, the overall mean density value is most likely indicative of the status of brook lamprey in the Boyne catchment

Extent and distribution of spawning nursery habitat	m^2 and occurrence	No decline in extent and distribution of spawning and nursery beds	This target is based on spawning and nursery bed mapping during targeted larval lamprey monitoring surveys. River lamprey spawn in clean gravels in flowing water where they excavate shallow nests. While coarse substrate is required for spawning, the close proximity of nursery areas comprising mainly sand/silt are necessary for the development of larvae. The 2015 Boyne survey recorded adequate spawning and nursery habitat availability within the catchment (Gallagher et al., 2016). However, the sequence of weirs in the lower main channel of the Boyne represents a significant impediment to upstream passage. In addition, this lower section of river is in a degraded hydromorphological state with impounding and, therefore, poor habitat availability for spawning

1106 Salmon *Salmo salar*

To restore the favourable conservation condition of Atlantic Salmon (*Salmo salar*) in River Boyne and River Blackwater SAC, which is defined by the following list of attributes and targets:

Attribute	Measure	Target	Notes
Distribution: extent of anadromy	Percentage of river accessible	100% of river channels down to second order accessible from estuary	Artificial barriers block salmons' upstream migration, thereby limiting species to lower stretches and restricting access to spawning areas. There are multiple barriers to fish migration in the Boyne system
Adult spawning fish	Number	Conservation limit (CL) for each system consistently exceeded	A conservation limit (CL) is defined by the North Atlantic Salmon Conservation Organisation (NASCO) as "the spawning stock level that produces long-term average maximum sustainable yield as derived from the adult to adult stock and recruitment relationship". The target is based on the Technical Expert Group on Salmon's (TEGOS) annual model output of CL attainment levels. See Gargan et al. (2021) for further details. Stock estimates are either derived from direct counts of adults (rod catch, fish counter) or indirectly by fry abundance counts. The Boyne is significantly below its CL
Salmon fry abundance	Number of fry/5 minutes electrofishing	Maintain or exceed 0+ fry mean catchment-wide abundance threshold value. Currently set at 17 salmon fry/5 minutes sampling	Target is threshold value for rivers currently exceeding their conservation limit (CL)
Out-migrating smolt abundance	Number	No significant decline	Smolt abundance can be negatively affected by a number of impacts such as estuarine pollution, predation and sea lice (*Lepeophtheirus salmonis*)
Number and distribution of redds	Number and occurrence	No decline in number and distribution of spawning redds due to anthropogenic causes	Salmon spawn in clean gravels. There is restricted habitat for salmon in the Boyne and habitat rehabilitation programmes have been undertaken in sections of the catchment
Water quality	EPA Q value	At least Q4 at all sites sampled by EPA	Q values based on triennial water quality surveys carried out by the Environmental Protection Agency (EPA)

1355 Otter *Lutra lutra*

To maintain the favourable conservation condition of Otter (*Lutra lutra*) in River Boyne and River Blackwater SAC, which is defined by the following list of attributes and targets:

Attribute	Measure	Target	Notes
Distribution	Percentage positive survey sites	No significant decline	Measure based on standard otter survey technique. Favourable Conservation Status (FCS) target, based on 1980/81 survey findings, is 88% in SACs. Current range is estimated at 93.6% (Reid et al., 2013)
Extent of terrestrial habitat	Hectares	No significant decline. Area mapped and calculated as 447.6ha along river banks/ lake shoreline/around ponds	No field survey. Areas mapped to include 10m terrestrial buffer, identified as critical for otters (NPWS, 2007), along rivers and around water bodies
Extent of freshwater (river) habitat	Kilometres	No significant decline. Length mapped and calculated as 263.3km	No field survey. River length calculated on the basis that otters will utilise freshwater habitats from estuary to headwaters (Chapman and Chapman, 1982)
Extent of freshwater (lake) habitat	Hectares	No significant decline. Area mapped and calculated as 31.6ha	No field survey. Area mapped based on evidence that otters tend to forage within 80m of the shoreline (NPWS, 2007)
Couching sites and holts	Number	No significant decline	Otters need lying up areas throughout their territory where they are secure from disturbance (Kruuk and Moorhouse, 1991; Kruuk, 2006)
Fish biomass available	Kilograms	No significant decline	Broad diet that varies locally and seasonally, but dominated by fish, in particular salmonids, eels and sticklebacks in freshwater (Bailey and Rochford, 2006; Reid et al., 2013)
Barriers to connectivity	Number	No significant increase	Otters will regularly commute across stretches of open water up to 500m, e.g. between the mainland and an island; between two islands; across an estuary (De Jongh and O'Neill, 2010). It is important that such commuting routes are not obstructed

National Bat Database of Ireland - O084751

Name	National Bat Database of Ireland
Grid Resolution	100
Grid	O084751
Site	Undisclosed
Dataset	National Bat Database of Ireland
Survey	All Ireland Daubentons Bat Waterways Survey
Precision	Undetermined
Recorder	Tina Aughney
Determiner	
Taxon	Pipistrellus pygmaeus
Common Name	Soprano Pipistrelle
Date	01/08/2010

Additional Attributes:

Determiner name	Tina Aughney
Survey name	All Ireland Daubentons Bat Waterways Survey
Type of roost	Transect

60 m

Scale: 1:2500 - Resolution: 100m

707885, 775493

Background

The National Biodiversity Data Centre is committed to the goals and principles of making biodiversity data openly and universally available. This commitment is given on the understanding that the provision of data will further the conservation of biological diversity.

This spreadsheet provides a summary of the data contained in the National Biodiversity Data Centre, maintained by the National Biodiversity Data Centre, for the given area of your query.

Use of this information is encouraged for decision making, research and sharing knowledge on Ireland's biodiversity. When using this information, please note:

- The information contained in this spreadsheet can only be considered a guide to the conservation importance or value of a given area, as the available data is unlikely to be systematic or complete.
- Absence of records of threatened or protected species from an area does not imply that they are not present within the given area. Their absence may be due to lack of adequate surveys of the area.
- The interpretation of the information generated in this query should be undertaken by a qualified ecologist to ensure its meaning is not misunderstood.
- The use of this information for decision making should in no way be seen as a substitute for appropriate contemporary field survey. It can, however, be used to prioritise elements of biodiversity for more detailed study.

Use of this information in reports or other published sources must be accompanied by an acknowledgement as follows:
'Information from the National Biodiversity Data Centre downloaded from Biodiversity Maps on [*insert date*].'

The Centre would welcome notification to info@biodiversityireland.ie of any reports or other publications in which this summary information is used.

Disclaimer

This website & mapping system is presented by the National Biodiversity Data Centre free of charge for the benefit of the public. The National Biodiversity Data Centre does not accept any liability for any injury, loss or damage of any kind incurred by use of or reliance on the information.

The National Biodiversity Data Centre accepts no liability for any interference with or damage to a user's computer system, software or data occurring in connection with this website. Users are encouraged to take appropriate and adequate precautions to ensure that whatever is selected from this site is free of viruses or other contamination that may interfere with or damage the user's computer system, software or data.

Quality of information

The National Biodiversity Data Centre makes every effort to ensure the quality of the information available on this website and updates the information regularly. Before relying on the information on this site, however, users should carefully evaluate its accuracy, currency, completeness and relevance for their purposes. The National Biodiversity Data Centre cannot guarantee and assumes no legal liability or responsibility for the accuracy, currency or completeness of the information.

To assist the Centre in the provision of high quality information, should you identify an error in any of the information provided, please notify the Centre and every effort will be made to rectify the error.

WRONG IMAGE PATH!

Irish Water gives this information as to the position of its underground network as a general guide only on the strict understanding that it is based on the best available information provided by each Local Authority in Ireland . It should not be relied upon in the event of excavations or other works being carried out in the vicinity of the network. The onus is on the parties carrying out the works to ensure the exact location of the network is identified prior to mechanical works being carried out. Service pipes are not generally shown but their presence should be anticipated. © Irish Water

IRISH WATER NOTICE

Irish Water gives this information as to the position of its underground network as a general guide only on the strict understanding that it is based on the best available information provided by each Local Authority in Ireland . It should not be relied upon in the event of excavations or other works being carried out in the vicinity of the network. The onus is on the parties carrying out the works to ensure the exact location of the network is identified prior to mechanical works being carried out. Service pipes are not generally shown but their presence should be anticipated. © Irish Water

JANUARY 2026

CONTENTS

1.0 SITE DISCRIPTION

1.1 St. Dominick's Park is a public park located along the south banks of the Boyne River at Rathmullen, Drogheda, Co. Louth. The location of the site is shown on Fig.1.1

1.2 The central feature of the park is a children's playground with associated car park facility. The existing layout of this area is shown on Fig.1.2

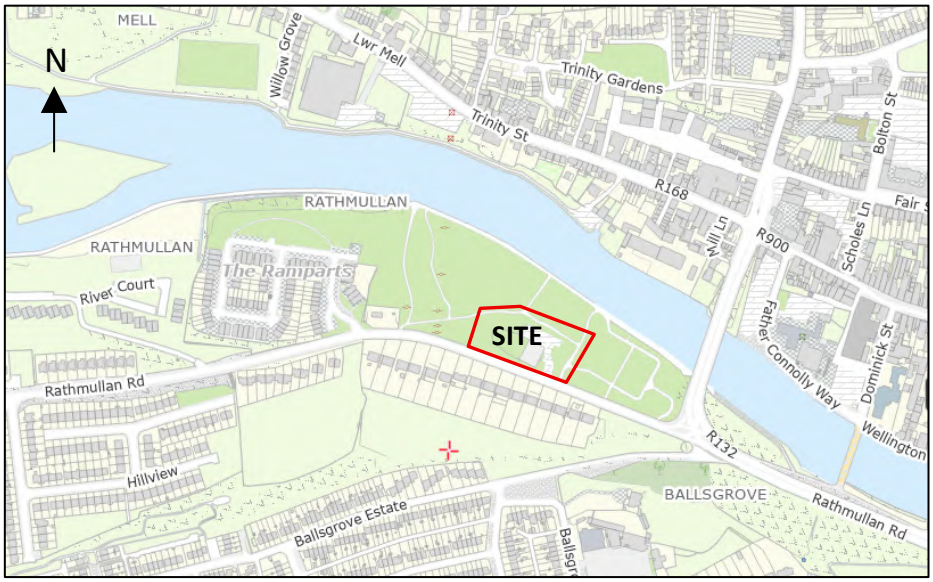

Fig.1.1 – Site Location Map

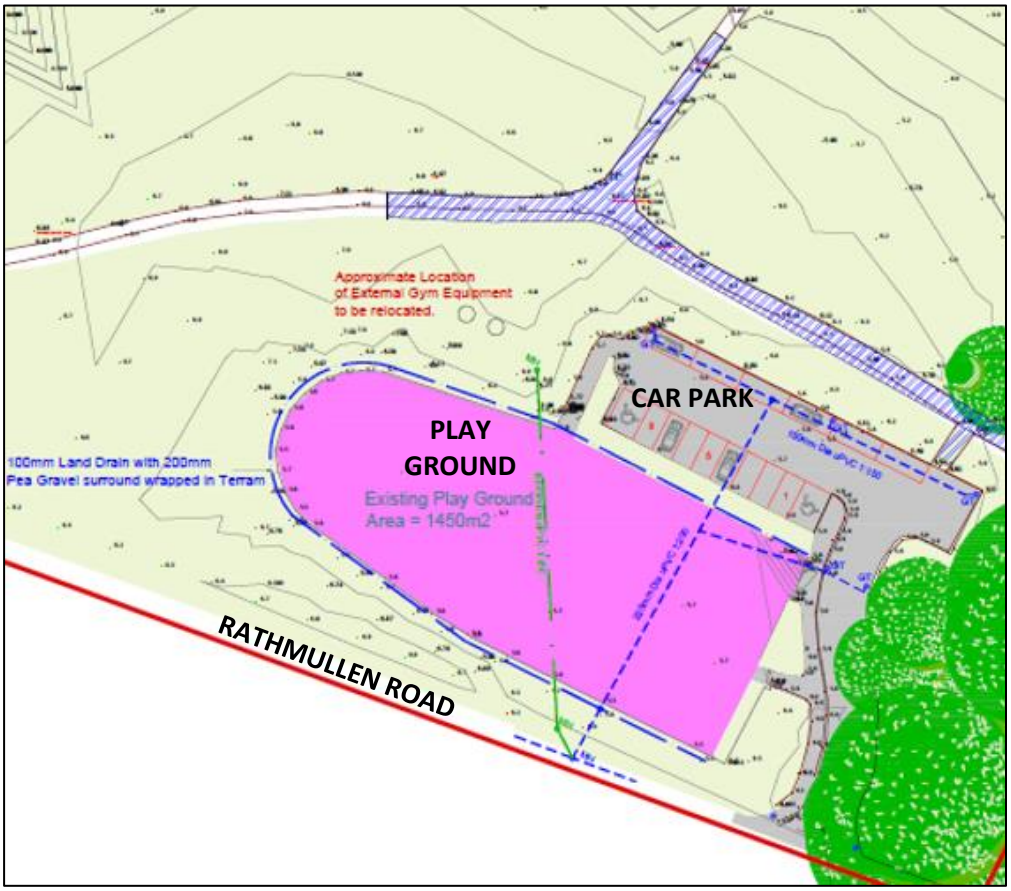

Fig.1.2 – Existing Site Layout

2.0 PROPOSED DEVELOPMENT

2.1 It is proposed to upgrade the existing facility by extending the playground, extending the car park, providing cycle parking facilities and installing Eco-Toilets.

2.2 The proposed Site Layout is shown on Fig.2.1

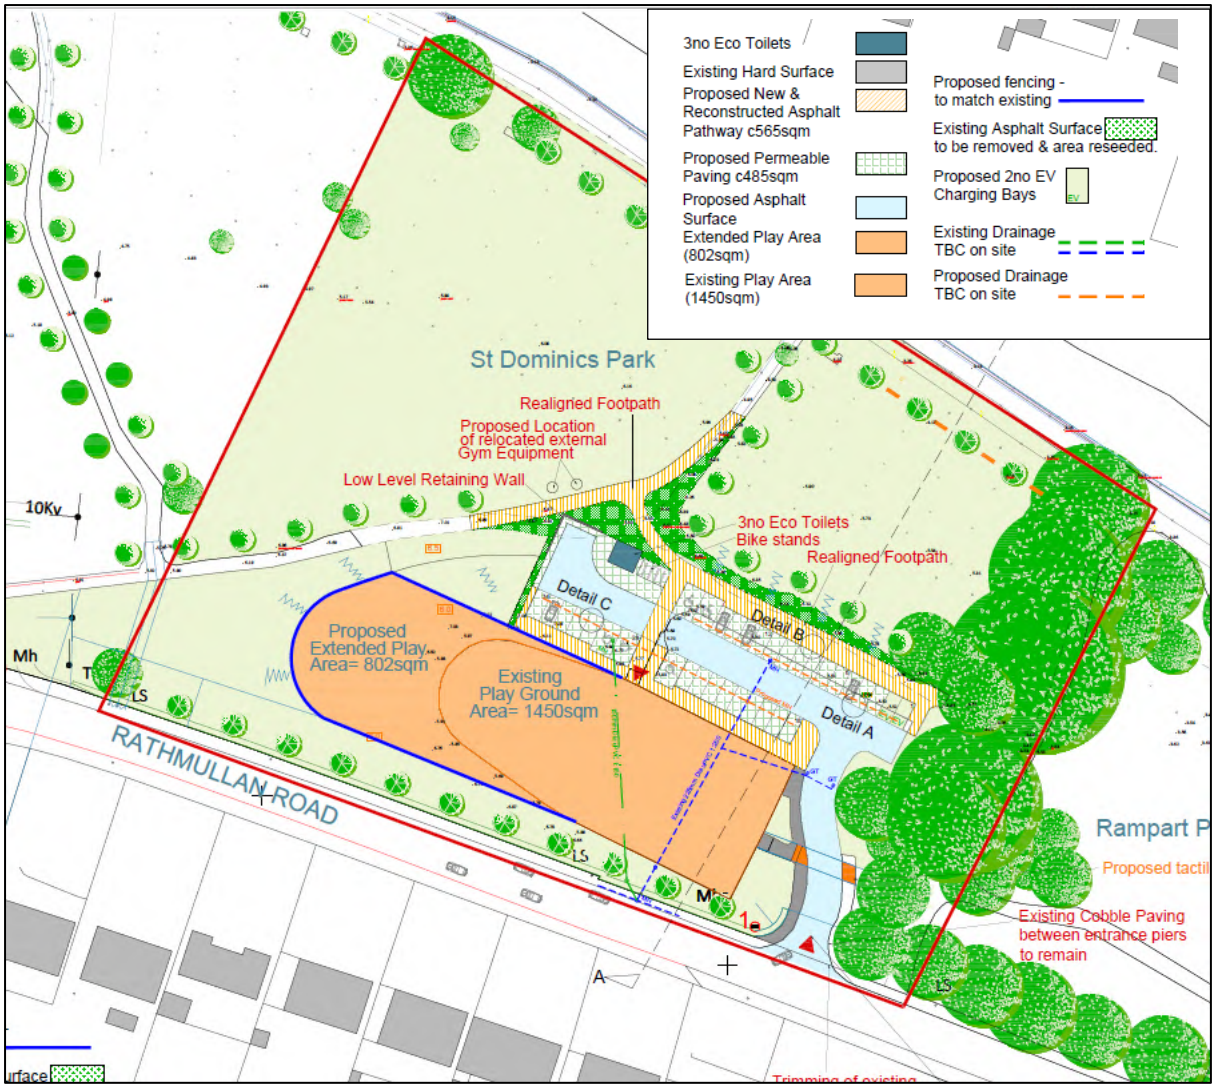

Fig.2.1 – Proposed Site Layout

3.0 INFILTRATION CHARACTERISTICS OF THE UNDERLYING SUB-SOIL

3.1 The infiltration characteristics of the underlying sub-soil at the site was determined by excavating a test hole (2.3m x 0.8m x 1.7m deep) within the site and carrying out an infiltration test in accordance with BRE 365. The test hole was located within the strip of grass to the north of the existing playground and south of the existing car park as shown on Fig.3.1. Views of the test hole are shown on Fig. 3.2

3.2 The subsoil was found to comprise of
0m – 0.30m Topsoil
0.3m – 1.3m Gravelly clay with cobbles
1.3m – 1.7m Silty Clay

No rock nor ground water was encountered in the test hole

3.3 The initial rate of water level drop was good with a drop of 0.17m within 40 minutes. The rate then significantly reduced with a further reduction of only 0.13m recorded over the next 120 minutes.

3.4 The initial drop of water occurred within the gravelly clay layer of the subsoil with the reduction in infiltration rate happening once the water level dropped into the lower silty clay layer. In essence, the test results show reasonable infiltration within the upper layers of the subsoil (< 1.3m) and more modest infiltration within the lower layer of the subsoil (>1.3m)

3.5 Calculations , carried out in accordance with BRE365, estimate the infiltration rate in each layer to be as follows:

Sub-Soil Layer	***Infiltration rate (m/s)***
Upper Layer (< 1.3m)	2.49 x 10-5
Lower Layer (>1.3m)	6.80 x 10-6

3.6 Full details of the Infiltration Test are attached as Appendix 1

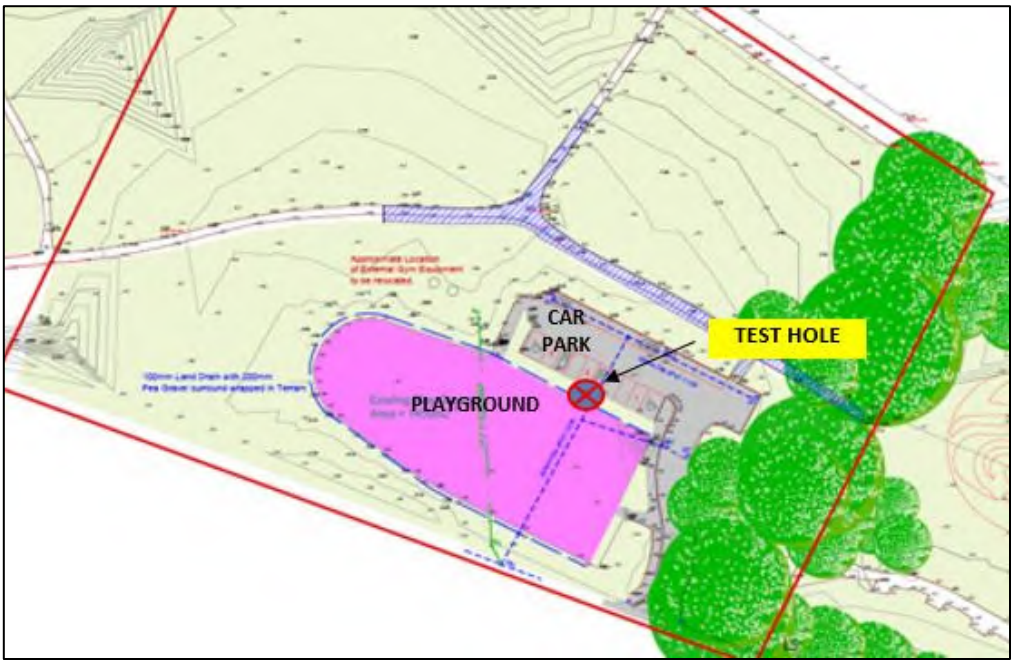

Fig. 3.1 – Test Hole Location

Fig. 3.2 – Views of Infiltration Test Hole

4.0 SURFACE WATER DRAINAGE DESIGN PROPOSAL

4.1 The low infiltration available within the sub-soil below 1.3m rules out the use of standard deep infiltration devices such as soakpits or soakage trenches to deal with surface water run-off generated from the development

4.2 It is therefore recommended that the surface water drainage proposal for the upgraded park facility avails of the favourable infiltration properties within the upper layer of the underlying sub-soil to the maximum possible extent through the construction of car park spaces and non-trafficked areas (footpaths, walkways, play area) using permeable surfaces as follows:

- Car park spaces – Permeable block paving Type 1
- New/Realigned Walkways – Permeable block paving Type 2 and/or porous asphaltic concrete
- Extended Play Area - porous asphaltic concrete

4.3 The selection of permeable paving is not deemed suitable for the access road and car park circulation aisles given it's the inferior structural strength. These surfaces should be constructed using standard asphaltic concrete material in accordance with DN-PAV-03021 (TII)

4.4 The crown of the access road shall be along its centreline with a 3% crossfall to each side. This crossfall shall continue into the car park spaces along each side. The cross fall shall allow run-off from the impermeable road carriageway to flow into the adjoining permeable car park space as shown on Fig. 4.1 and Fig.4.2.
Design Note: *It is an established design threshold that 1 sq.m of permeable surface can accommodate run-off from 2 sq.m of adjoining impermeable surface. The 0.6 : 1 ratio of impermeable surface area to permeable surface area proposed in this case is significantly below the 2 : 1 ratio threshold.*

4.5 The incorporation of permeable paving will meet SuDS objectives with respect to quantity, quality and amenity as follows:

- Quantity: Provides an underground storage area until full infiltrating of run-off into the sub-soil is completed

- Quality: Improves the quality of the water in two ways:
  - The stones within the sub-base act as a filter medium which remove heavy particles such as silt and heavy metals.
  - Over time microbial organisms begin to cultivate in the pavement which break down hydrocarbon leaks such as exhaust fumes and sump oil drips

- Amenity: visually differentiates parking areas from road surface. combines hard landscaping with a SuDS drainage solution

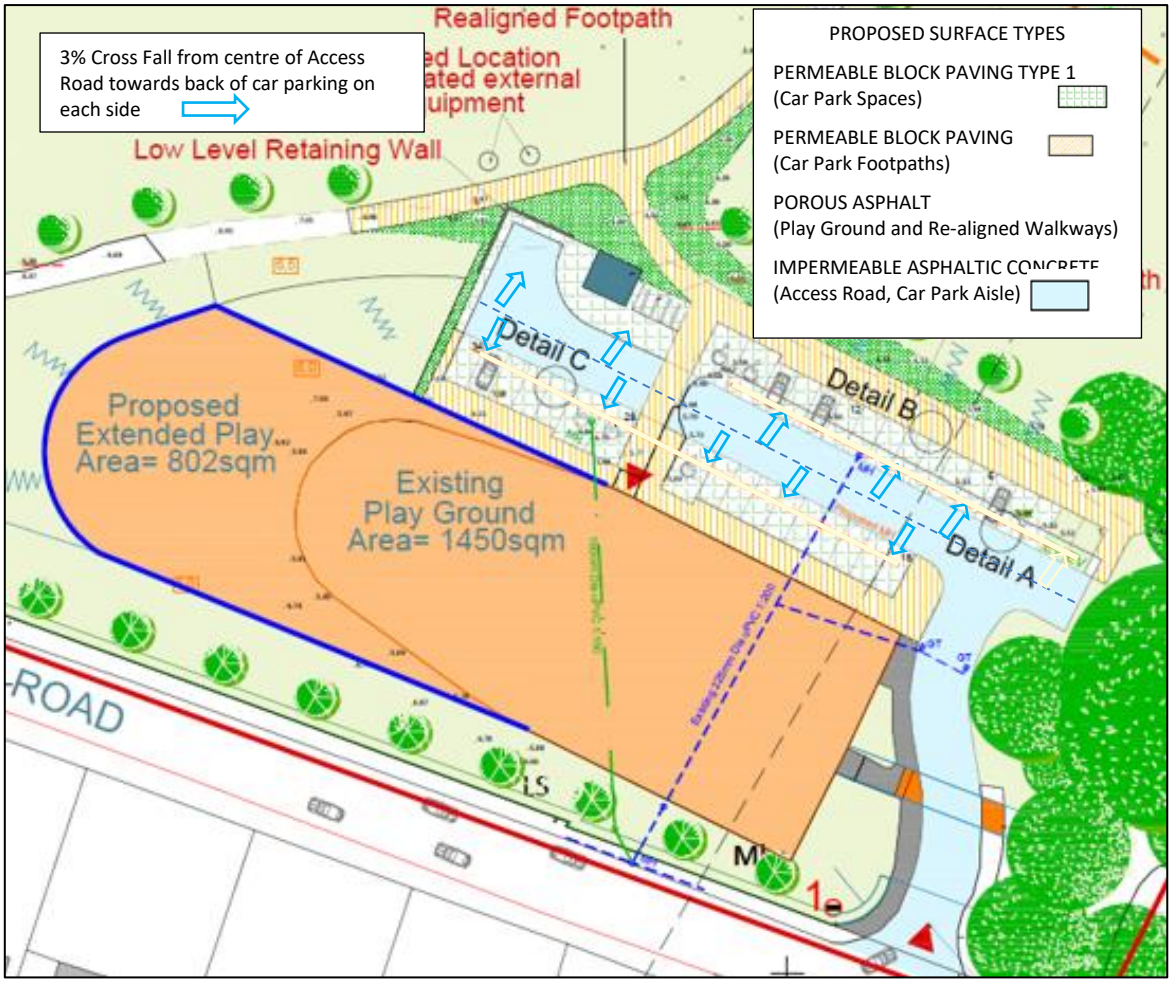

Fig.4.1 –Surface Water Proposal – Recommended Surface Types (Schematic only – NTS)

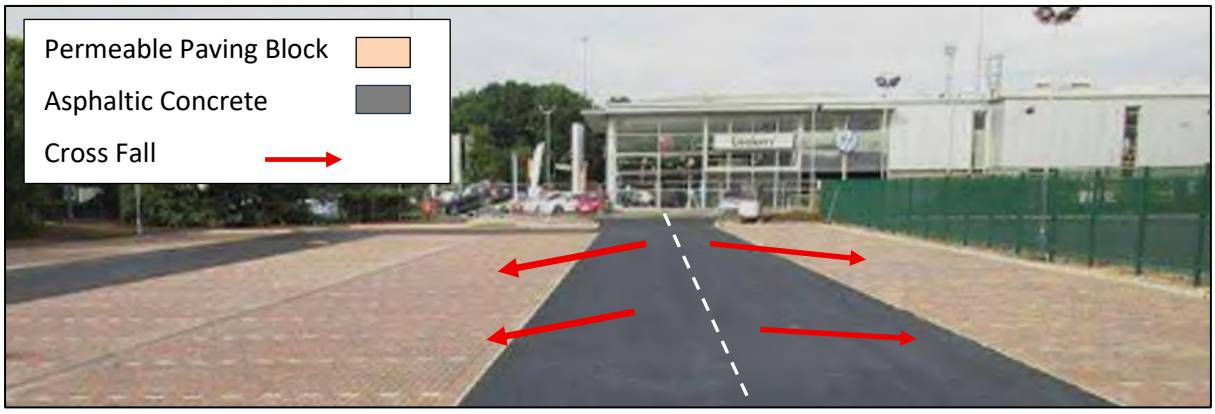


4.2 Proposed SW Design Proposal for Car Park – Indicative Only

5.0 DESIGN OF PERMABLE PAVING

(a) Design of Permeable Block Paving Type 1 – Car Park Spaces

(i) Structural Design

5.1 The structural design of the permeable paving is based on the methodology set out in Section 8.0 of 'Design & Construction of Concrete Block Permeable Paving' (Interpave). The key design issues are the strength of the sub-grade (CBR value) and the traffic loading to be placed on the surface. Relevant Design Charts are attached as Appendix 2

5.2 *Sub-Grade Strength* - The trial pit excavated within the site for the soil infiltration test identified the upper layers of the subsoil to be a gravelly clay. Such a material generally has a CGR as a poorly graded sand/gravel (SP classification). Soil of this classification generally has a CBR value in the range of 5% - 10%. It is proposed to adopt a lower value of CBR = 5% for design purposes.

5.3 *Traffic Loading* - A Traffic Loading Category of 3 ('small car arks subject to car and light van access') shall be adopted as per Table 4 of the Interpave design guide.

5.4 The appropriate permeable paving design from a structural perspective given the combination of a minimum CBR of 5.0 and a Traffic Loading of 3 e is as follows as per Table 4 of the Interpave Design Guid:

- 60mm permeable block paving , complying with BS EN1338:2003, on
- 50mm laying course (6.3mm – 2.0mm grit) complying with BS EN 13242 on
- 225mm Coarse Granular Aggregate (4/20mm) complying with BS EN 13242, on
- Non-woven permeable geotextile (Terram 1000 or similar)

(ii) Hydraulic Design

5.5 It has been determined that a 225mm sub-base depth is required from a structural perspective. It is necessary to determine whether the depth of storage available within the 225mm deep layer of coarse granular aggregate is sufficient from a hydraulic design perspective

5.6 Each car park space shall provide a $15m^2$ surface area of porous paving. The design allows for run-off the adjoining impermeable road carriageway ($10.0m^2$) to discharge into each car park space as per Fig. 4.1. In essence $15m^2$ of porous paving shall deal with run off from a total area of $25.0m^2$

5.7 It has been determined from the BRE 365 test that the sub-soil has an infiltration rate of 2.48×10^{-5}m/s. It is proposed to apply a Factor of Safety of 2.50 to this value and to base the design calculation of an infiltration rate of 1.0×10^{-5}m/s. On this basis, run-off shall infiltrate through the base of each car park space at a rate of $0.54m^3$/hr (1.0×10^{-5} m/s x 3600 x $15m^2$)

5.8 Run-off shall be stored within the 30% voids provided within the coarse aggregate in cases where the quantum of run-off exceeds the discharge rate of $0.54m^3$/hr through the base of each car park space. Calculations determining the storage required under a range of rainfall

events based on a 1 in 100 year rainfall return period and a further 20% allowance for climate change are as follows:

Storm Duration	*Rainfall 1 in 100 yea[1] (mm)*	*Rainfall + 20%*	*Contrib. Area per car park space (sq.m)*	*Total Vol of Rainfall (cu.m)*	*Rate of Discharge into underlying sub-soil per car park space (0.54 m^3/hr)*	*Storage Required Cu.m*
10 mins	16.7	20.0	25.0	0.50	0.09	0.41
15 min	19.6	23.5	25.0	0.59	0.13	0.46
30 mins	24.2	29.0	25.0	0.73	0.27	0.46
1 hour	29.8	35.8	25.0	0.90	0.54	0.36
2 hour	36.8	44.2	25.0	1.11	1.08	0.03
3 hour	41.6	49.9	25.0	1.25	1.62	-0.37
4 hour	45.4	54.5	25.0	1.36	2.16	-0.8

Note 1: Met. Eireann Data for Rathmullen - (Full Rainfall Data Set provided as Appendix 3)

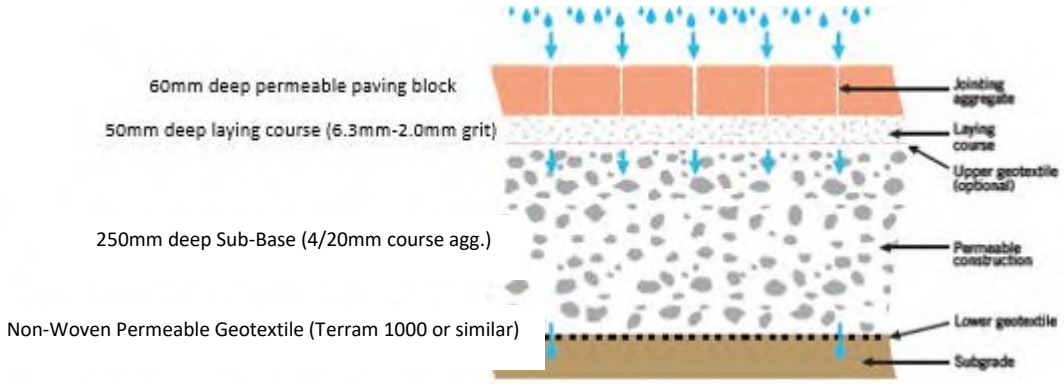
5.9 The calculations show that storage shall be required only during short intense rainfall events of less than 1 hour with a maximum storage requirement of 0.46m^3.
This equates to a stored water deeth of circa 105mm as follows:

- Depth of water stored (m) = 0.46/(15 x 0.3) = 0.102m (say 105mm)

5.10 This 105mm depth is less than the 225mm depth of coarse aggregate sub-base required under the pavement strength design criterion. However, design guides consider it prudent to have a freeboard of between 100mm - 150mm above the TWL of stored water and the top of the sub-base. The selection of a 145mm freeboard would give a 250mm depth of sub-base required from an hydraulic perspective (105mm + 145mm = 250mm). It is therefore necessary to increase the depth of porous sub-base from 225mm to 250mm ensure sufficient attenuation storage is provided in the stone later

5.11 The revised construction design for the permeable paved car park areas is as follows:

- 60mm permeable block paving , complying with BS EN1338:2003, on
- 50mm laying course (6.3mm – 2.0mm grit) complying with BS EN 13242 on
- 250mm Coarse Granular Aggregate (4/20mm) complying with BS EN 13242, on
- Non- woven permeable geotextile (Terram 1000 or similar)



5.12 The half empty time for the stored water shall be (0.46)(0.5)/(0.54) = 0.43 hours. This is significantly less than the design theshold of 24 hours and therefore acceptable

(b) Design of Permeable Block Paving Type 2 – Walkways

5.13 Permeable block paved walkways should have a similar design to that outlined above for car park spaces

- 60mm permeable block paving , complying with BS EN1338:2003, on
- 50mm laying course (6.3mm – 2.0mm grit) complying with BS EN 13242 on
- 250mm Coarse Granular Aggregate (4/20mm) complying with BS EN 13242, on
- Non- woven permeable geotextile (Terram 1000 or similar)

(c) Design of Permeable Asphaltic Concrete Surfaces

5.14 Any permeable asphalt surface should have the following layers:

- 60mm porous asphalt - PA 14 surf complying with BS EN 13108-7 and Chapter 6 of CC-SPW-00900 (TII) on
- 250mm Coarse Granular Aggregate (4/20mm) complying with BS EN 13242, on
- Non-woven permeable geotextile (Terram 1000 or similar)

6.0 PROVISION FOR EMERGENCY CONDITIONS / EXTREME RAINFALL EVENTS

6.1 It is noted that the current drainage of the car park area is via a standard surface water drainage network whereby run-off is collected in a series of road gullies and piped into a surface water drainage pipe that runs along the Rathmullen Road.

6.2 While the proposed surface water regime has a robust design its efficient operation is dependent on the performance of the permeable paving. This performance may be adversely impacted over time by the build up of grit and silt on the road surface.

6.3 It is therefore considered prudent that the existing surface water drainage infrastructure is retained and extended into the new car park area to act as an emergenct overflow route for run-off in the event of the performance of the permeable paving being reduced and/or to cater for extreme rainfall events. Road gullies should be located in optimum locations to capture run-off in the event that the permeable paving system is overwhelmed by extreme rainfall or its condition has deteriorated.

6.4 A schematic sketch of the proposed emergency back up arrangement is shown on Fig. 6.1

Fig.6.1 – Proposed Alterations of Existing SW Drainage Network to provide an emergency overflow route (Schematic only)

7.0 SUMMARY

7.1 Two different sub-soil types were encountered in the test hole excavated for the infiltration test

<1.3m Gravelly clay with cobbles

>1.3m Silty Clay

7.2 Calculations , carried out in accordance with BRE365, estimate the infiltration rate in each layer to be as follows:

Sub-Soil Layer	***Infiltration rate (m/s)***
Upper Layer (< 1.3m)	2.49 x 10-5
Lower Layer (>1.3m)	6.80 x 10-6

7.3 The low infiltration available within the sub-soil below 1.3m rules out the use of standard deep infiltration devices such as soakpits or soakage trenches to deal with surface water run-off generated from the development

7.4 It is therefore recommended that the surface water drainage proposal for the upgraded park facility avails of the favourable infiltration properties within the upper layer of the underlying sub-soil to the maximum possible extent through the construction of car park spaces and non-trafficked areas (footpaths, walkways, play area) using permeable surfaces as shown on Fig. 7.1 and as follows:

- Car park spaces – Permeable block paving Type 1
- New/Realigned Walkways – Permeable block paving Type 2 and/or porous asphaltic concrete
- Extended Play Area - porous asphaltic concrete

7.5 Design calculations, based on 1 in 100 year rainfall events (including a 20% allowance for increased rain due to climate change), determine the following construction detail for the surface types from a structural and hydraulic perspective:

(i) Permeable Block Paving Type 1 and Type 2 (Refer to Fig.7.2)

- 60mm permeable block paving , complying with BS EN1338:2003, on
- 50mm laying course (6.3mm – 2.0mm grit) complying with BS EN 13242 on
- 250mm Coarse Granular Aggregate (4/20mm) complying with BS EN 13242, on
- Non- woven permeable geotextile (Terram 1000 or similar)

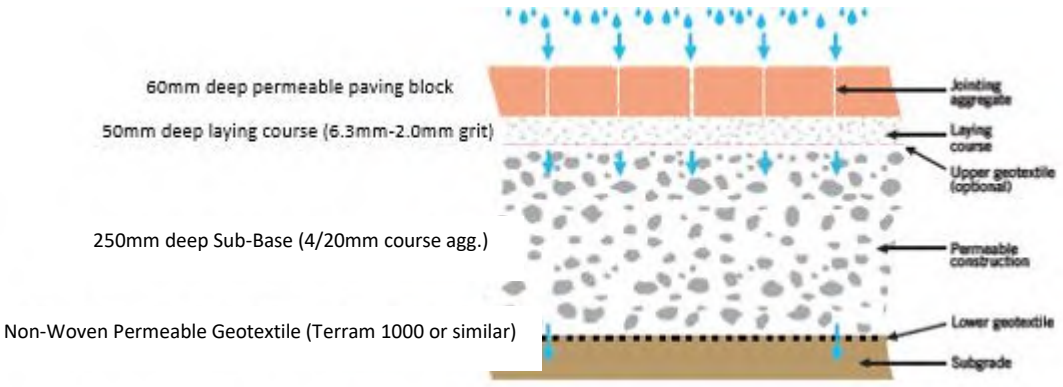


Fig.7.2 Recommended Construction Detail for Permeable Block Paving Surfaces Type 1 and Type 2

(ii) porous asphalt surface

- 60mm porous asphalt - PA 14 surf complying with BS EN 13108-7 and Chapter 6 of CC-SPW-00900 (TII) on
- 250mm Coarse Granular Aggregate (4/20mm) complying with BS EN 13242, on
- Non-woven permeable geotextile (Terram 1000 or similar)

7.6 It is recommended that the existing surface water drainage piped network is retained and extended, as shown on Fig.7.3, to offer an emergency overflow route for run-off in the event of the performance of the permeable paving being reduced and/or to cater for extreme events during which permeable paving system is overwhelmed by extreme rainfall or the infiltration capacity of the surface has deteriorated due to build up of grit/silt.

6.7 Overall, the design proposal represents a robust design solution that ensures that all generated surface water run-off shall be dealt with within the site in a manner that respects SuDs principles with respect to quantity, quality and amenity, but which also avails of existing infrastructure to offer an emergency overflow route for run-off in the event of a critical failure of the infiltration performance of the permeable surfaces.

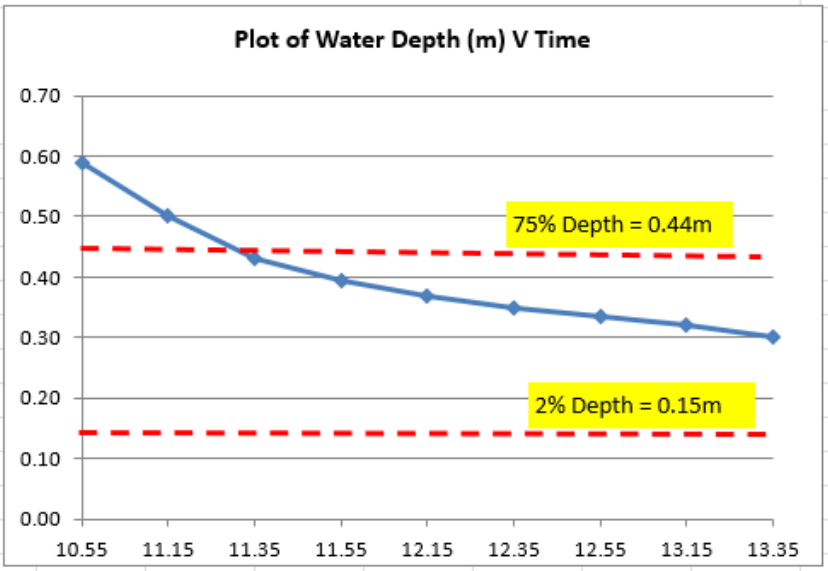
BRE 365 INFILTRATION TEST AT ST. DOMINICS PARK, DROGHEDA, CO.LOUTH

Date: 03/12/25
Client: Louth Co. Co.
Test Carried Out by: Louth Co.Co
Test Hole Location: Grass Strip along north side of existing Play Area (south side of ex. Car Park)
Dimensions of Test Hole: 2.3m x 0.80m x 1.7m deep
Description of sub-soil: topsoil (0m - 0. 30m), gravelly clay with cobbles (0.30m - 1.3m), silty clay (>1.3m)
Depth to Groundwater: None encountered
Depth to Rock: No rock encountered

Time	*Depth of water(m)*
10.55	0.59
11.15	0.50
11.35	0.43
11.55	0.40
12.15	0.37
12.35	0.35
12.55	0.34
13.15	0.32
13.35	0.30



Calculations for Upper Layer of Subsoil
(Water drop from 0.89m - 0.43m)

	TEST DATA & RESULTS
Length of Test Hole (m)	2.3
Width of Test Hole (m)	0.8
100% depth water (m)	0.59
75% depth (m)	0.55
25% depth (m)	0.47
Time to drop 75% to 25% (mins)	21
Depth of water infiltrated during test period	0.085
Vol of water infiltrated during test period (m3)	0.1564
Surface Area through which water infiltrates during test period (m2)	4.9865
Soil Infiltration Rate (m/min)	0.00149
Soil Infiltration Rate (m/sec)	2.489E-05

Calculations for Lower Layer of Sub-Soil
Drop from 0.43m to 0.30m

	TEST DATA & RESULTS
Length of Test Hole (m)	2.3
Width of Test Hole (m)	0.8
100% depth water (m)	0.43
75% depth (m)	0.397
25% depth (m)	0.333
